

Future Skills Training Program

Data Science and Analytics

Topic:- Basics of Python

Dr. Sunil Joshi

Agenda

Python Basic

- String

Python 3 – Strings

- **Strings are amongst the most popular types in Python.**
- **We can create them simply by enclosing characters in quotes.**
- **Python treats single quotes the same as double quotes.**
- **Creating strings is as simple as assigning a value to a variable.**
- **example**

```
var1 = 'Hello World!'
```

```
var2 = "Python Programming"
```

Updating Strings

- You can "update" an existing string by (re)assigning a variable to another string. The new
- value can be related to its previous value or to a completely different string altogether.
- For example-

```
var1 = 'Hello World!'
```

```
print ('Updated String :- ', var1[:6] + 'Python')
```

- When the above code is executed, it produces the following result-

Updated String :- Hello Python

String Special Operators

Operator	Description	Example
+	Concatenation - Adds values on either side of the operator	a + b will give HelloPython
*	Repetition - Creates new strings, concatenating multiple copies of the same string	a*2 will give - HelloHello
[]	Slice - Gives the character from the given index	a[1] will give e
[:]	Range Slice - Gives the characters from the given range	a[1:4] will give ell
in	Membership - Returns true if a character exists in the given string	H in a will give 1
not in	Membership - Returns true if a character does not exist in the given string	M not in a will give 1
r/R	Raw String - Suppresses actual meaning of Escape characters. The syntax for raw strings is exactly the same as for normal strings with the exception of the raw string operator, the letter "r," which precedes the quotation marks. The "r" can be lowercase (r) or uppercase (R) and must be placed immediately preceding the first quote mark.	print r'\n' prints \n and print R'\n'prints \n

String Special Operators

%	Format - Performs String formatting	See next section
---	-------------------------------------	----------------------------------

String Formatting Operator

- One of Python's coolest features is the string format operator `%`. This operator is unique
- to strings and makes up for the pack of having functions from C's `printf()` family. Following
- is a simple example –

```
print ('My name is %s and age is %d year!' % ('Sunil', 42))
```

String Formatting Operator

Format Symbol	Conversion
<code>%c</code>	character
<code>%s</code>	string conversion via <code>str()</code> prior to formatting
<code>%i</code>	signed decimal integer
<code>%d</code>	signed decimal integer
<code>%u</code>	unsigned decimal integer
<code>%o</code>	octal integer
<code>%x</code>	hexadecimal integer (lowercase letters)
<code>%X</code>	hexadecimal integer (UPPERcase letters)
<code>%e</code>	exponential notation (with lowercase 'e')

String Formatting Operator

<code>%E</code>	exponential notation (with UPPERCASE 'E')
<code>%f</code>	floating point real number
<code>%g</code>	the shorter of <code>%f</code> and <code>%e</code>
<code>%G</code>	the shorter of <code>%f</code> and <code>%E</code>

Other supported symbols and functionality are listed in the following table

Built-in String Methods

S. No.	Methods with Description
1	capitalize() Capitalizes first letter of string
2	center(width, fillchar) Returns a string padded with <i>fillchar</i> with the original string centered to a total of <i>width</i> columns.
3	count(str, beg= 0,end=len(string)) Counts how many times str occurs in string or in a substring of string if starting index beg and ending index end are given.
4	decode(encoding='UTF-8',errors='strict') Decodes the string using the codec registered for encoding. encoding defaults to the default string encoding.
5	encode(encoding='UTF-8',errors='strict') Returns encoded string version of string; on error, default is to raise a ValueError unless errors is given with 'ignore' or 'replace'.
6	endswith(suffix, beg=0, end=len(string))

Built-in String Methods

7	expandtabs(tabsize=8) Expands tabs in string to multiple spaces; defaults to 8 spaces per tab if tabsize not provided.
8	find(str, beg=0 end=len(string)) Determine if str occurs in string or in a substring of string if starting index beg and ending index end are given returns index if found and -1 otherwise.
9	index(str, beg=0, end=len(string)) Same as find(), but raises an exception if str not found.
10	isalnum() Returns true if string has at least 1 character and all characters are alphanumeric and false otherwise.
11	isalpha() Returns true if string has at least 1 character and all characters are alphabetic and false otherwise.

Built-in String Methods

12	isdigit() Returns true if the string contains only digits and false otherwise.
13	islower() Returns true if string has at least 1 cased character and all cased characters are in lowercase and false otherwise.
14	isnumeric() Returns true if a unicode string contains only numeric characters and false otherwise.

Built-in String Methods

15	isspace() Returns true if string contains only whitespace characters and false otherwise.
16	istitle() Returns true if string is properly "titlecased" and false otherwise.
17	isupper() Returns true if string has at least one cased character and all cased characters are in uppercase and false otherwise.
18	join(seq) Merges (concatenates) the string representations of elements in sequence seq into a string, with separator string.
19	len(string) Returns the length of the string

Built-in String Methods

20	ljust(width[, fillchar]) Returns a space-padded string with the original string left-justified to a total of width columns.
21	lower() Converts all uppercase letters in string to lowercase.
22	lstrip() Removes all leading whitespace in string.
23	maketrans() Returns a translation table to be used in translate function.

Built-in String Methods

24	max(str) Returns the max alphabetical character from the string str.
25	min(str) Returns the min alphabetical character from the string str.
26	replace(old, new [, max]) Replaces all occurrences of old in string with new or at most max occurrences if max given.
27	rfind(str, beg=0, end=len(string)) Same as find(), but search backwards in string.
28	rindex(str, beg=0, end=len(string)) Same as index(), but search backwards in string.

Built-in String Methods

29	<code>rjust(width,[, fillchar])</code> Returns a space-padded string with the original string right-justified to a total of width columns.
30	<code>rstrip()</code> Removes all trailing whitespace of string.
31	<code>split(str="", num=string.count(str))</code> Splits string according to delimiter str (space if not provided) and returns list of substrings; split into at most num substrings if given.
32	<code>splitlines(num=string.count('\n'))</code> Splits string at all (or num) NEWLINEs and returns a list of each line with NEWLINEs removed.

Built-in String Methods

33	startswith(str, beg=0, end=len(string)) Determines if string or a substring of string (if starting index beg and ending index end are given) starts with substring str; returns true if so and false otherwise.
34	strip([chars]) Performs both lstrip() and rstrip() on string
35	swapcase() Inverts case for all letters in string.
36	title() Returns "titlecased" version of string, that is, all words begin with uppercase and the rest are lowercase.

Built-in String Methods

37	translate(table, deletechars="") Translates string according to translation table str(256 chars), removing those in the del string.
38	upper() Converts lowercase letters in string to uppercase.
39	zfill (width) Returns original string leftpadded with zeros to a total of width characters; intended for numbers, zfill() retains any sign given (less one zero).
40	isdecimal() Returns true if a unicode string contains only decimal characters and false otherwise.

Home Work

- 1. Python program to check if a string is palindrome or not**
- 2. Python program to Check if a Substring is Present in a Given String**
- 3. Find length of a string in python.**
- 4. Python program to print even length words in a string**
- 5. Python Program to accept the strings which contains all vowels**
- 6. Python Program Count the Number of matching characters in a pair of string**
- 7. Remove all duplicates from a given string in Python**
- 8. Find words which are greater than given length k**
- 9. Python program to split and join a string**
- 10. Python program Check if a given string is binary string or not**
- 11. Python Counter program which Find all duplicate characters in string.**
